CHAKRABORTI AND DEEPAK G. BHATIA UNIVERSITY OF MANITOBA U2.2 Introduction: In recent years, theoretical and experimental data on the anatomy and physiology of plant reproduction has seen an enormous change. Different fundamental concepts and mechanisms are being challenged, and new ones are being described. It is now accepted that it is not the physical model of sexual reproduction which is the most essential part of the theory of plant reproduction but its conceptualization. It is a fact that what is known of the sexual reproduction of plants is an example of cooperation between cells from different species. In terms of cooperation, only three kinds of cells are involved in sexual reproduction: egg, sperm and ovules; and two are male and two female. In all organisms, plant cells contain genetic information which is passed on to offspring. This was the original idea of Mendel, but in plants, information from the female parent is more important, and is generally passed on by the male parent to the female. The theory of plant reproduction is now expanding to other organelles and to the entire cell. Information on cell development is being extended to include mitosis, meiosis and its various types of cell division. The theory of the cell and its development is being reinterpreted and extended to include the role of genes in the expression of development. What has been originally proposed as a special cellular organelle, the plastid, is now being studied with a new respect. Of course, as with other organs and tissues, sexual reproduction is no longer seen as the only means of obtaining offspring. Indeed, the entire cell is being reexamined from the point of view of reproduction. For many reasons, it is important to understand the basic concepts of plant reproduction. In the first place, it is necessary to understand how we reproduce, and then to know how a plant reproduces. Finally, it is vital to know what we can learn from the plants 82157476af
